Script-Controlled ACL: Restricting Record Access Based on Field Value

1. Brainstorming & Ideation Phase

The project is based on improving record-level security in ServiceNow by controlling access to records according to the value stored in a specific field. In a standard ACL configuration, access may depend mainly on roles and conditions, but some business requirements need additional scripted validation.

The main idea is to use a **Script-Controlled Access Control List (ACL)** to evaluate the current record and determine whether the logged-in user should be allowed to access it. The script checks the required field value and returns an access decision based on the defined security rule.

The project user story is: **As a ServiceNow administrator, I want record access to be controlled based on a field value so that users can view or modify only the records they are authorized to access.** This is intended to strengthen data security and reduce the possibility of unauthorized record access.

The proposed solution focuses on creating a simple and maintainable ACL script that works together with existing roles and conditions. For example, access can be permitted only when a record has a particular classification, assignment group, department, or access-level value.

The expected outcome is a more controlled and consistent security model in which record access is automatically evaluated at runtime, reducing manual intervention and helping protect sensitive business information.
