Script-Controlled ACL - Restrict Record Access Based on Field Value

8. Project Demonstration Phase

The project demonstration presents the completed Script-Controlled ACL implementation in ServiceNow. The demonstration can begin by showing the Access Control configuration and the ACL created to restrict record access based on a field value.

The demonstration shows the selected table and access operation, along with the configured script that evaluates the required field value. The ACL condition is reviewed to show how the access decision is controlled by the field value.

After the ACL is configured, the demonstration shows records with different field values and tests access to those records. The user access result is verified to confirm that records meeting the defined field-value condition are accessible while restricted records are denied.

The record is opened to demonstrate the applied access control, and the ACL script and field value are reviewed to verify the relationship between the configured condition and the resulting record access.

The demonstration therefore shows the complete documented process from configuring the Script-Controlled ACL and defining the field-value rule to testing record access and verifying the expected access restriction.
