3. Project Design Phase

The project design defines how the ServiceNow Script Controller ACL will restrict record access based on a specific field value. The ACL is designed to control whether a user can access a record by checking the value stored in the selected field. When a user attempts to access a record, the Script Controller evaluates the field value and verifies the defined access condition. If the condition is satisfied, access to the record is allowed; otherwise, access is restricted. The ACL can be configured for the required table and access operation, such as Read, Write, Create, or Delete. The field value is checked dynamically during the access request, allowing the security rule to be applied according to the required business condition. This design provides controlled access to records and prevents unauthorized users from viewing or modifying restricted information. By using a Script Controller, the access condition can be customized according to the field value and the user's requirements. The solution therefore improves record-level security and ensures that users can access only the records permitted by the defined field-based access rule.
