Script-controlled ACL – Restrict Record Access Based onField Value

4.Project Development Phase

The project development phase implements record-level security in ServiceNow using a script-controlled Access Control List (ACL). The main objective is to restrict access to records based on a specific field value.

The first activity is to open ServiceNow and navigate to System Security, then open Access Control (ACL). A new ACL is created for the required table and record operation, such as read access.

The ACL is configured with the required role or condition and a script is added to check the value of the selected field. The script allows access only when the field value satisfies the defined condition. If the condition is not satisfied, access to the record is restricted.

The ACL is then saved and tested with suitable user records. The test confirms that users can access records when the field value matches the defined rule and cannot access records when it does not.

The final check is to verify that the script-controlled ACL works correctly without affecting authorized access. This ensures that record access is controlled according to the required field value.
