Script-controlled ACL – Restrict Record Access Based on Field Value

5. Project Development Phase

The development phase implements the required access control in ServiceNow. The main development component is a Script-controlled Access Control List (ACL), which is used to restrict record access based on a field value.

A new ACL is created for the required table and record operation. The ACL is configured to control access using a script condition. The script checks the value of a specific field in the record and allows access only when the required condition is satisfied.

For example, the ACL can check whether a field value matches a particular value or condition. If the condition is true, the user is allowed to access the record. If the condition is false, access to the record is restricted.

After configuring the script, the ACL is saved and tested with different field values and user access levels. This ensures that users can access only the records that satisfy the defined condition.

This development implementation provides field-based record security and helps prevent unauthorized users from accessing restricted records.
