Script-Controlled ACL: Restrict Record Access Based on Field Value

6. Project Testing Phase

The testing phase verifies the Script-controlled Access Control List (ACL) by checking whether record access is correctly restricted based on a field value.

The test begins by opening the target record and checking the configured field value. The ACL script evaluates this value and determines whether the current user is allowed to access the record.

Records that contain the permitted field value should be accessible to authorized users. Records with a restricted or non-matching field value should not be accessible when the ACL condition is not satisfied.

The ACL is then tested with different users and field values to verify that the access rules work as configured. The record visibility and access behavior are checked after each test.

The documented testing is therefore based on confirming that the Script-controlled ACL correctly grants or restricts record access according to the configured field value.
