Script-Controlled ACL – Restrict Record Access Based on Field Value

7. Project Documentation Phase

The project documentation records the purpose, configuration, script logic, and outcome of the ServiceNow access control implementation. The project addresses the requirement to restrict record access based on a specific field value and documents the use of a Script-Controlled Access Control List (ACL).

The documented project objective is to provide controlled access to records by evaluating a field value through an ACL script, reduce unauthorised record access, enforce security requirements, and improve consistency in ServiceNow data protection.

The implementation documentation includes the creation and configuration of the ACL, selection of the appropriate table and operation, and use of a scripted condition to evaluate the target field value. The script determines whether the current user is permitted to access the record based on the defined field-value condition.

The documentation also records the process of testing the ACL with records having different field values and verifying the resulting access behaviour. The allowed and restricted scenarios are validated to confirm that the script-controlled ACL is applied as intended.

The final project conclusion states that implementing a Script-Controlled ACL to restrict record access based on field value strengthens ServiceNow data security, enforces field-based access rules, reduces unintended access, and provides controlled and consistent record visibility.
